- Large-scale production capacity.
- Cost-effective when feedstocks are readily available.

Challenges

- High energy consumption.
- Significant CO₂ emissions.
- Complex product separation and purification processes.
- Variability in olefin yields depending on feedstock and operating conditions.

2. Fluid Catalytic Cracking (FCC)

Overview

FCC is a refining process primarily used to convert heavier hydrocarbon fractions into lighter, more valuable products like gasoline, olefins, and propylene.

Process Details

- Feedstocks: Vacuum gas oils, residual oils, and other heavy fractions.
- Mechanism: Catalytic cracking in a fluidized bed reactor with a zeolite catalyst.

Advantages

- Utilizes heavy refinery streams, adding value.
- Integrated into existing refineries, reducing capital costs.

Challenges

- Lower selectivity for propylene compared to other routes.
- Catalyst deactivation over time.
- Complex product separation.

3. Dehydrogenation of Propane (Propanes Dehydrogenation - PDH)

Overview

Propane dehydrogenation is an endothermic catalytic process that converts propane directly into propylene and hydrogen.

Process Details

- Feedstock: Propane-rich streams, often sourced from natural gas liquids or refinery streams.
- Reaction Conditions: Temperatures of 500-700°C, with catalysts such as chromium-based or platinum-based systems.
- Reaction Equation: $C_3H_8 \rightarrow C_3H_6 + H_2$

Advantages

- High selectivity toward propylene (>85%).
- On-purpose production, independent of crude oil refining.
- Suitable for regions with abundant propane supplies.

Challenges

- Significant heat input required.
- Catalyst deactivation due to coking.
- Hydrogen byproduct, which can be utilized or require management.
- Capital-intensive plants.

4. Methanol-to-Propylene (MTP) Technology

Overview

MTP technology involves converting methanol—primarily derived from natural gas, coal, or biomass—into propylene via catalytic processes.

Process Details

- Feedstocks: Methanol, produced from syngas.
- Reaction Pathways: Catalytic conversion over specific zeolites (e.g., ZSM-5), leading directly to propylene.

- Advantages: Flexibility in feedstock origin; suitability for regions with abundant methanol production.

Advantages

- On-demand, flexible production.
- Lower capital costs compared to dehydrogenation plants.
- Potential for integrated methanol and olefin production.

Challenges

- Catalyst life and selectivity issues.
- Market competition with traditional olefin routes.
- Dependence on methanol supply infrastructure.

Emerging and Alternative Routes

1. Ethylene Oligomerization and Conversion

Ethylene produced via steam cracking can be oligomerized to higher olefins, which can then be selectively cracked or dehydrogenated into propylene.

Advantages

- Adds value to ethylene streams.
- Can be integrated into existing ethylene production facilities.

Challenges

- Additional process steps.
- Catalyst development and process optimization needed.

2. Bio-based Routes

Research is ongoing into bio-derived feedstocks, such as biomass fermentation products, to produce propylene through catalytic conversions.

Advantages

- Potential for renewable, low-carbon propylene.
- Diversification of supply sources.

Challenges

- Technological maturity.
- Economic competitiveness.
