Question What are the primary functions of the human skeletal system? The human skeletal system provides structural support, protects vital organs, facilitates movement by serving as an attachment point for muscles, stores minerals like calcium and phosphorus, and produces blood cells within the bone marrow. **Answer** How do the muscles work together to produce movement? Muscles work through coordinated contractions of agonist and antagonist pairs. When one muscle contracts

(agonist), its counterpart (antagonist) relaxes, allowing smooth and controlled movement across joints. What is the role of the nervous system in human physiology? The nervous system controls and coordinates body activities by transmitting electrical signals between the brain, spinal cord, and nerves, allowing for perception, movement, and regulation of internal processes. How do the respiratory and circulatory systems work together? The respiratory system facilitates gas exchange by bringing oxygen into the lungs and removing carbon dioxide, while the circulatory system transports these gases via blood to and from tissues, ensuring cellular respiration and metabolic processes continue efficiently. What are the different types of joints in the human body? The main types of joints include fibrous joints (immovable), cartilaginous joints (partially movable), and synovial joints (freely movable), each allowing various degrees of movement and stability. How does the cardiovascular system maintain blood pressure? The cardiovascular system maintains blood pressure through mechanisms like adjusting heart rate and stroke volume, and regulating blood vessel diameter via vasoconstriction and vasodilation, influenced by neural and hormonal signals. What is the significance of the human integumentary system? The integumentary system, comprising the skin, hair, nails, and glands, protects underlying tissues, regulates temperature, prevents water loss, and provides sensory information about the environment.
